

## On $n$ -in-countable bases

S.A. PEREGUDOV

*Abstract.* Some results concerning spaces with countably weakly uniform bases are generalized for spaces with  $n$ -in-countable ones.

*Keywords:* weakly uniform base,  $n$ -in-countable base, countably compact space, separable space

*Classification:* Primary 54A25; Secondary 54D30

All spaces in the paper are assumed to be  $T_1$ . If  $\tau$  and  $\lambda$  are cardinals, then one says that a family  $\mathcal{B}$  of sets is  $\tau$ -in- $\lambda$  if for every set  $A$  of cardinality  $\tau$ ,  $A \subset B$  holds for no more than  $\lambda$  members  $B \in \mathcal{B}$ .  $\tau$ -in- $< \lambda$  is defined similarly. One says that a family is  $\tau$ -in-countable in place of  $\tau$ -in- $\omega$  and that a family is  $\tau$ -in-finite in place of  $\tau$ -in- $< \omega$ . A 2-in-finite family is called *weakly uniform* and a 2-in-countable family is also called *countably weakly uniform*.

We are going to extend results of paper [6] on spaces with *countably weakly uniform bases* to spaces with  *$n$ -in-countable bases*, where  $n$  is a natural number. A few results concern  *$n$ -in-finite bases*.

**Lemma 1.** *Let  $n \geq 1$  be a natural number. An  $n$ -in-countable open family in a separable space is countable.*

PROOF: It is evident. □

**Theorem 1.** *Let  $n \geq 1$  be a natural number. A regular countably compact space with an  $n$ -in-countable  $T_1$ -separating open cover is metrizable.*

PROOF: Let  $X$  be a regular countably compact space and let  $\mathcal{B}$  be its  $n$ -in-countable  $T_1$ -separating open cover. Denote by  $\mathcal{L}(X)$  the set of all nonisolated points of  $X$ . It is evident that if  $x \in \mathcal{L}(X)$  then  $ord(x, \mathcal{B}) \leq \min\{|A| : x \text{ is an accumulation point of } A\}$ . Let us consider the set  $Z = \{x \in \mathcal{L}(X) : ord(x, \mathcal{B}) \leq \omega\}$ . Because  $X$  is regular countably compact,  $\bar{Z} = \mathcal{L}(X)$ . Now, by analogy with the proof of Miscenco’s theorem [3] with using Lemma 1 one can prove that there exists a countable set  $Y \subset Z$  such that  $\bar{Y} = \mathcal{L}(X)$ . Hence  $|\{B \in \mathcal{B} : B \cap \mathcal{L}(X) \neq \emptyset\}| \leq \omega$ . We can assume that if  $B \in \mathcal{B}$  and  $B \cap \mathcal{L}(X) = \emptyset$  then  $B$  is an one-point set. Hence  $\mathcal{B}$  is countable. Therefore  $X$  is metrizable. □

**Corollary 1** ([1]). *Let  $n \geq 1$  be a natural number. A regular countably compact space with an  $n$ -in-countable base is metrizable.*

Later on we will denote by  $\mathcal{I}(X)$  the set of all isolated points of a space  $X$ .

**Lemma 2.** *Let  $n \geq 1$  be a natural number. Let  $X$  be a space with an  $n$ -in-countable base  $\mathcal{B}$  and let  $|\mathcal{I}(X)| = \tau$ , where  $\tau$  is an uncountable cardinal. Then  $X$  has an  $n$ -in-countable base  $\mathcal{B}^*$  such that for each  $x \in \mathcal{I}(X)$ ,  $\text{ord}(x, \mathcal{B}^*) < \tau$ .*

PROOF: Let  $\mathcal{I}(X) = \{x_\xi : \xi < \tau\}$ . Let us define  $\mathcal{B}_0 = \{B \in \mathcal{B} : x_0 \in B\}$ . Let  $\eta < \tau$ . Assume that  $\mathcal{B}_\xi$  are defined for each  $\xi < \eta$ . Then we define  $\mathcal{B}_\eta = \{B \in \mathcal{B} : x_\eta \in B, B \notin \mathcal{B}_\xi \text{ under } \xi < \eta\}$ . Now put  $\mathcal{B}_\xi^1 = \{B \setminus \{x_\xi\} : B \in \mathcal{B}_\xi\}$  for each  $\xi < \tau$  and  $\mathcal{B}^1 = \bigcup \{\mathcal{B}_\xi^1 : \xi < \tau\}$ . It is evident that if  $A \subset \mathcal{I}(X)$  and  $|A| = n - 1$  then  $|\{B \in \mathcal{B}^1 : A \subset B\}| < \tau$ . Repeating this step  $n - 1$  times (of course we assume  $n \geq 2$ ), we obtain a family  $\mathcal{B}^{(n-1)}$  such that  $\mathcal{B}^* = \mathcal{B}^{(n-1)} \cup \{B \in \mathcal{B} : B \cap \mathcal{I}(X) = \emptyset\} \cup \{\{x\} : x \in \mathcal{I}(X)\}$  is a base with all the required properties.  $\square$

**Lemma 3.** *Let  $n \geq 1$  be a natural number. Let  $X$  be a space with an  $n$ -in-countable base  $\mathcal{B}$  and let  $|\mathcal{I}(X)| \leq \omega$ . Then  $X$  has an  $n$ -in-countable base  $\mathcal{B}^*$  such that for each  $x \in \mathcal{I}(X)$ ,  $\text{ord}(x, \mathcal{B}^*) \leq \omega$ .*

PROOF: The statement can be proved just as Lemma 2.  $\square$

**Theorem 2.** *Let  $n \geq 1$  be a natural number. A regular locally separable space with an  $n$ -in-countable base is metrizable.*

PROOF: The statement is proved in just the same way as Theorem from [7] with using above-mentioned Lemmas 1, 2, and 3. Here is a sketch of the proof. By Lemma 1 the space is locally metrizable. Hence every its  $n$ -in-countable base has a countable order at each nonisolated point. Let us maintain induction on the cardinality of the set of all isolated points. Let a space  $X$  satisfy the assumptions of Theorem 2, and let  $|\mathcal{I}(X)| \leq \omega$ . Then with respect to the above remark and by Lemma 3,  $X$  has a point-countable base. Therefore  $X$  is divided into a disjoint family of open metrizable subspaces. Consequently,  $X$  is metrizable. Now, let  $\tau$  be an uncountable cardinal. Let us assume that the statement of the theorem is true for each cardinal  $\lambda < \tau$ . Suppose now that  $|\mathcal{I}(X)| = \tau$ . We will consider two cases.

*Case 1.  $\tau$  is regular.* By Lemmas 1 and 2 there is a base  $\mathcal{B}$  of  $X$  of order  $< \tau$  at each point of  $X$ . Without loss of generality we may assume that every element of the base is separable. For every  $B^* \in \mathcal{B}$  define a family  $\mathcal{E}(B^*)$  in the following way:  $\mathcal{E}_0(B^*) = \{B^*\}$ ,  $\mathcal{E}_1(B^*) = \{B \in \mathcal{B} : B \cap B^* \neq \emptyset\}$ ,  $\dots$ ,  $\mathcal{E}_n(B^*) = \{B \in \mathcal{B} : B \cap (\bigcup \mathcal{E}_{n-1}) \neq \emptyset\}$ , etc.,  $\mathcal{E}(B^*) = \bigcup \{\mathcal{E}_n(B^*) : n \in \omega\}$ . Then we have  $|\mathcal{E}(B^*)| < \tau$ , and  $\bigcup \mathcal{E}(B^*)$  has less than  $\tau$  isolated points. It follows that  $\bigcup \mathcal{E}(B^*)$  is metrizable, hence  $X$  is metrizable too.

*Case 2.  $\tau$  is singular.* Then there are a cardinal  $\lambda < \tau$  and a partition  $\{I_\xi : \xi < \lambda\}$  of the set  $\mathcal{I}(X)$  such that  $|I_\xi| = \tau_\xi < \tau$ . Let  $\mathcal{B}$  be a base of  $X$  with the same properties as in Case 1. Fix an ordinal  $\xi < \lambda$ . For each point  $a \in I_\xi$  put  $\mathcal{S}_a = \{B \in \mathcal{B} : a \in B\}$ . Put  $A_\eta = \bigcup \{\mathcal{S}_a : |\mathcal{S}_a| < \tau_\eta\}$ . Since  $A_\eta$  is an open subspace of  $X$ , which has the set of all isolated points of cardinality less than  $\tau$ , it is metrizable. Hence, the space  $G_\xi = \bigcup \{B \in \mathcal{B} : B \cap I_\xi \neq \emptyset\} = \bigcup \{A_\eta : \eta < \lambda\}$

has a base of order no more than  $\lambda$  at each its point. It follows that the space  $G = \bigcup\{G_\xi : \xi < \lambda\} = \bigcup\{B \in \mathcal{B} : B \cap \mathcal{I}(X) \neq \emptyset\}$  has a base  $\mathcal{U}$  of order no more than  $\lambda$  at each its point. Without loss of generality we may assume that every element of the base is separable. In the same way as in Case 1 it can be proved that  $G$  is metrizable. Because  $X \setminus G$  is contained in an open subspace of  $X$  without isolated points, it is metrizable. Thus,  $X$  is the union of two open locally separable metrizable subspaces. Hence  $X$  is metrizable.  $\square$

**Corollary 2.** *Let  $n \geq 1$  be a natural number. A regular space which admits an  $n$ -in-countable cover of open separable metrizable subspaces is metrizable.*

**Corollary 3.** *Let  $n \geq 1$  be a natural number. A regular locally countably compact space with an  $n$ -in-countable base is metrizable.*

**Corollary 4** ([2]). *Let  $n \geq 1$  be a natural number. A Hausdorff locally compact space with an  $n$ -in-countable base is metrizable.*

**Lemma 4** (MA +  $\neg$ CH). *Let  $n \geq 1$  be a natural number. If  $X$  is a Čech-complete space with  $c(X) = \omega$ , then every open  $n$ -in-countable family of  $X$  is countable.*

PROOF: Under  $n = 1$  this is a result of Shapirovskii [9]. Then the statement is proved by induction on  $n$ .  $\square$

It follows from [8] that the statement of Lemma 4 is false under  $\neg$ SH even if  $n = 1$ .

**Theorem 3** (MA +  $\neg$ CH). *Let  $n \geq 1$  be a natural number. Suppose that  $X$  is a regular space which is locally Čech-complete and locally has the Souslin property. If  $X$  has an  $n$ -in-countable base, then  $X$  is metrizable.*

PROOF: The statement follows from Lemma 4 and Theorem 2.  $\square$

**Theorem 4.** *Let  $n \geq 1$  be a natural number. Every pseudocompact space with an  $n$ -in-finite base is Čech complete first countable.*

PROOF: Let  $X$  be a pseudocompact space and  $\mathcal{B}$  be an  $n$ -in-finite base for  $X$ . For each  $B \in \mathcal{B}$  choose an open in  $\beta X$  set  $B'$  such that  $B = X \cap B'$ , and consider the family  $\mathcal{B}'$  consisting of such sets. We show that the family  $\mathcal{B}'$  is  $n$ -in-finite in  $\beta X$ . Let  $A \subset \beta X$  and let  $|A| = n$ . Let  $\mathcal{S}$  be an infinite countable subfamily of the family  $\mathcal{B}$ . Denote by  $F$  the set  $\bigcap \mathcal{S} \cap A$ . By definition, the cardinality of  $F$  is less than  $n$ . Then  $G = \bigcap\{B' \setminus F : B \in \mathcal{S}\} \subset \beta X \setminus X$ . Because  $X$  is pseudocompact, the set  $G$  being a  $G_\delta$ -set of  $\beta X$  that is contained in  $\beta X \setminus X$  is empty by the well known result of Hewitt [5]. Thus  $\mathcal{B}'$  is an  $n$ -in-finite family in  $\beta X$ . The same arguments show that the family  $\mathcal{B}'$  has finite order at each point of  $\beta X \setminus X$ . Denote by  $\mathcal{I}$  the set of all isolated points of  $X$  and define  $F_m = \{x \in \beta X : ord(x, \mathcal{B}') \leq m\} \setminus \mathcal{I}$ . Because  $\mathcal{I}$  is open in  $\beta X$ , each  $F_m$  is a closed subset of  $\beta X$ . Moreover,  $\beta X \setminus X = \bigcup\{F_m : m \in \omega\}$ . So  $X$  is Čech

complete; therefore,  $X$  is a  $k$ -space. It is evident that a  $k$ -space with an  $n$ -infinite base is first countable.  $\square$

**Corollary 5.** *Let  $n \geq 1$  be a natural number. Every submetacompact pseudo-compact space with an  $n$ -infinite base is metrizable.*

**Theorem 5.** *Let  $n \geq 2$  be a natural number. Every space  $X$  with an  $n$ -infinite base has cardinality at most  $\exp_{n-1}(L(X))$ , where  $L(X)$  is the Lindelöf degree of  $X$ .*

PROOF: Let  $\mathcal{B}$  be an  $n$ -infinite base of  $X$ . Put  $\tau = L(X)$ . We will use the theorem of Erdős and Rado:  $(\exp_{n-1}(\tau))^+ \rightarrow (\tau^+)_\tau^n$  ([4]). Let us assume that  $|X| > \exp_{n-1}(\tau)$ . Consider a mapping  $P : [X]^n \rightarrow \omega$  defined by the rule:  $A \mapsto |\{B \in \mathcal{B} : A \subset B\}|$ . There exists a homogeneous with respect to  $P$  set  $H$  of cardinality  $\tau^+$ . It is easy to show that the set  $H$  is a closed discrete subset of  $X$ , a contradiction.  $\square$

Let us note that there exists an example of a Hausdorff Lindelöf space with a weakly uniform base which is not first countable ([6]).
